#### Ziyi Fang

# **Linear Regression**

For this lab, we will be working with a data set from the UCI (University of California, Irvine) Machine Learning repository (see website here (http://archive.ics.uci.edu/ml/datasets/Abalone)). The full data set consists of 4,177 observations of abalone in Tasmania. (Fun fact: Tasmania (https://en.wikipedia.org/wiki/Tasmania) supplies about 25% of the yearly world abalone harvest.)

Fig 1. Inside of an abalone shell.

The age of an abalone is typically determined by cutting the shell open and counting the number of rings with a microscope. The purpose of this data set is to determine whether abalone age (number of rings + 1.5) can be accurately predicted using other, easier-to-obtain information about the abalone.

The full abalone data set is located in the  $\data$  subdirectory. Read it into R using  $read_{csv()}$ . Take a moment to read through the codebook (  $abalone_{codebook.txt}$ ) and familiarize yourself with the variable definitions.

Make sure you load the tidyverse and tidymodels!

```
Hide

library(tidyverse)
library(tidymodels)
library(recipes)
library(rsample)
library(parsnip)

Hide

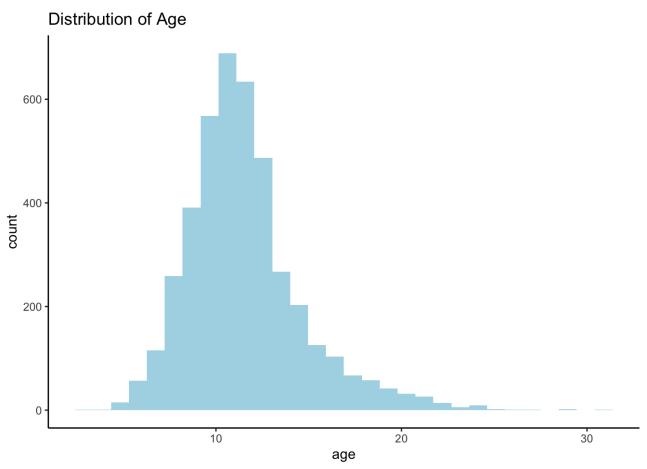

setwd("~/Desktop")
abalone<- read_csv("abalone.csv")</pre>
```

## **Question 1**

Your goal is to predict abalone age, which is calculated as the number of rings plus 1.5. Notice there currently is no age variable in the data set. Add age to the data set.

Assess and describe the distribution of age.

```
Hide
abalone <- abalone %>% mutate(age = rings + 1.5)
summary(abalone$age)
##
      Min. 1st Qu. Median
                               Mean 3rd Qu.
                                               Max.
      2.50
                     10.50
                                              30.50
##
              9.50
                              11.43
                                      12.50
                                                                            Hide
sd(abalone$age)
## [1] 3.224169
                                                                            Hide
ggplot(abalone, aes(x = age)) + geom_histogram(fill = "lightblue") +
  theme_classic() +
  labs(title = "Distribution of Age")
```

Hide

#Distribution of age is roughly normally distributed, slightly skewed #mean is 11.43, standard devition is 3.22

## Question 2

Split the abalone data into a training set and a testing set. Use stratified sampling. You should decide on appropriate percentages for splitting the data.

Remember that you'll need to set a seed at the beginning of the document to reproduce your results.

Hide

```
set.seed(468)

abalone_split<- initial_split(abalone, strata = age, prop = .8)
train<- training(abalone_split)
test<- testing(abalone_split)</pre>
```

### Question 3

Using the **training** data, create a recipe predicting the outcome variable, <code>age</code>, with all other predictor variables. Note that you should not include <code>rings</code> to predict <code>age</code>. Explain why you shouldn't use <code>rings</code> to predict <code>age</code>.

Steps for your recipe:

- dummy code any categorical predictors
- 2. create interactions between
  - type and shucked weight,
  - longest shell and diameter,
  - o shucked weight and shell weight
- 3. center all predictors, and
- 4. scale all predictors.

You'll need to investigate the tidymodels documentation to find the appropriate step functions to use.

Hide

#You should not use rings to predict age because age is a function of rings. You would be able to create a model that would perfectly predict age if you used rings as an input.

```
train<- train %>% dplyr::select(-c('rings'))
```

Hide

```
abalone_recipe<- recipe(age ~ ., data = train) %>%
    step_interact(terms = ~ type:shucked_weight) %>%
    step_interact(terms = ~ longest_shell:diameter) %>%
    step_interact(terms = ~ shucked_weight:shell_weight) %>%
    step_center(all_numeric(), -age) %>%
    step_scale(all_numeric(), -age) %>%
    step_dummy(all_nominal_predictors()) %>%
    step_dummy(all_nominal_predictors()) %>%
    update_role(type, new_role = "predictor") %>%
    prep(training = train) %>%
    prep()

#train_prep<- prep(abalone_recipe, training = train)
#train_final<- bake(train_prep, train)

#test_prep<- prep(abalone_recipe, training = test)
#test_final<- bake(train_prep, test)</pre>
```

### **Question 4**

Create and store a linear regression object using the "lm" engine.

Hide

```
lm_model<- linear_reg() %>% set_engine("lm") %>% set_mode("regression")
```

# **Question 5**

Now:

- 1. set up an empty workflow,
- 2. add the model you created in Question 4, and
- 3. add the recipe that you created in Question 3.

Hide

```
lm_wflow<- workflow() %>%
  add_recipe(abalone_recipe) %>%
  add_model(lm_model)
```

# **Question 6**

Use your fit() object to predict the age of a hypothetical female abalone with longest\_shell = 0.50, diameter = 0.10, height = 0.30, whole\_weight = 4, shucked\_weight = 1, viscera\_weight = 2, shell\_weight = 1.

Hide

```
test<- test %>% select(-c(rings))
df = data.frame(type = c("F","M","I"), longest_shell = c(0.50, .50, .10), di
ameter = c(0.10, .10,.10), height = c(0.30, .30,.30), whole_weight = c(4, 4,
4 ), shucked_weight = c(1,1,1 ), viscera_weight = c(2,2,2), shell_weight = c
(1,1,1))
lm_fit<- fit(lm_wflow,data = train)
lm_predict<- predict(lm_fit,new_data = test)
lm_predict_train<- predict(lm_fit,new_data = train)
newObsPrediction<- predict(lm_fit,new_data = df)</pre>
```

### Question 7

Now you want to assess your model's performance. To do this, use the yardstick package:

- 1. Create a metric set that includes  $R^2$ , RMSE (root mean squared error), and MAE (mean absolute error).
- 2. Use predict() and bind\_cols() to create a tibble of your model's predicted values from the **training data** along with the actual observed ages (these are needed to assess your model's performance).
- 3. Finally, apply your metric set to the tibble, report the results, and interpret the  $R^2$  value.

Hide

```
age_metrics<- metric_set(rmse,mae,rsq)
#tibble of actual and predictions for training data
df2<- tibble(actuals = train$age, predictions = lm_predict_train $>$ as_vect
or())
df2 $>$ age_metrics(truth = actuals, estimate = predictions)
```

```
## # A tibble: 3 × 3
     .metric .estimator .estimate
##
     <chr>
             <chr>
##
                            <dh1>
             standard
                            2.15
## 1 rmse
## 2 mae
            standard
                            1.54
                            0.557
## 3 rsq
             standard
```

Hide

# Rsq is equal to 0,5568951, which indicates that about half of the variabil ity in the outcome data cannot be explained by the model.

# Required for 231 Students

In lecture, we presented the general bias-variance tradeoff, which takes the form:

$$E[(y_0 - \hat{f}(x_0))^2] = Var(\hat{f}(x_0)) + [Bias(\hat{f}(x_0))]^2 + Var(\epsilon)$$

where the underlying model  $Y = f(X) + \epsilon$  satisfies the following:

•  $\epsilon$  is a zero-mean random noise term and X is non-random (all randomness in Y comes from  $\epsilon$ );

- $(x_0, y_0)$  represents a test observation, independent of the training set, drawn from the same model:
- $\hat{f}(.)$  is the estimate of f obtained from the training set.

#### **Question 8**

Which term(s) in the bias-variance tradeoff above represent the reproducible error? Which term(s) represent the irreducible error?

#### **Question 9**

Using the bias-variance tradeoff above, demonstrate that the expected test error is always at least as large as the irreducible error.

#### Question 10

Prove the bias-variance tradeoff.

Hints:

- use the definition of  $Bias(\hat{f}(x_0)) = E[\hat{f}(x_0)] f(x_0)$ ;
- reorganize terms in the expected test error by adding and subtracting  $E[\hat{f}(x_0)]$
